Abstract

Lactic acid fermentation includes several reactions in association with the microorganism growth. A kinetic study was performed of the utilisation of multiple substrates to lactic acid using Lactobacillus delbrueckii. Batch fermentation was performed to study effect of different substrates such as glucose, fructose and sucrose. The objective of this research is to study kinetics grow microbial. An anaerobic fermentation were studied in 3 litres stirred fermentor (Biostat B Model) with working volume of 1 liter, temperature = 40°C, pH = 6.0, inoculum size = 5%, sugar concentration = 20 g/L. During the first hours of fermentation, glucose and fructose accumulated in the medium and the rate of hydrolysis of sucrose to glucose and fructose was faster than conversion of these substrate. The maximum concentration of glucose and fructose was 5.82 and 5.14 g/L respectively. The sucrose, glucose, and fructose consumption completely utilized at 56, 68, and 104 hours, respectively. Kinetic parameter for maximum specific growth rate in glucose, fructose and sucrose is 0.083, 0.024, and 0.024 (h^-1), respectively. The saturation constant is 4.64, 3.41, and 1.36 g/L.

Keywords: Kinetic Study, Sugars. Lactic Acid, Maximum Specific Growth Rate, Saturation Constant

Abstrak

Fermentasi asam laktat melibatkan banyak reaksi dalam pertumbuhan mikroorganisme. Studi kinetika reaksi tentang kinerja penggunaan berbagai substrat untuk memproduksi asam laktat dengan Lactobacillus delbrueckii. Substrat yang digunakan adalah glukosa, fruktosa, dan sukrosa, dengan proses fermentasi curah. Penelitian ini bertujuan memelajari kinetika pertumbuhan mikroba. Fermentasi anaerobik dilakukan dalam fermentor 3 liter (Biostat B Model) dengan volume total 1 liter, temperatur = 40°C, pH = 6.0, konsentrasi inoculum = 5%, konsentrasi gula = 20 g/L. Selama jatuh pertama fermentasi, glukosa dan fruktosa diakumulasi dalam medium dan laju reaksi hidrolisis sukrosa menjadi glukosa dan fruktosa sangat cepat dibandingkan dengan konversi substrat ini. Konsentrasi glukosa dan fruktosa adalah 5.82 and 5.14 g/L. Waktu yang dibutuhkan sukrosa, glukosa dan fruktosa masing-masing adalah 56, 68, dan 104 jam. Parameter kinetika untuk laju pertumbuhan spesifik maksimum dalam medium glukosa, fruktosa, dan sukrosa masing-masing adalah 0.083, 0.024, dan 0.024 (h^-1). Konstanta saturasi adalah 4.64, 3.41, dan 1.36.

Kata Kunci: Kinetika Reaksi, Gula, Asam Laktat, Laju Pertumbuhan Spesifik Maksimum, Konstanta Saturasi
1. Introduction

The methods for the preparation of lactic acid are divided into two groups, biochemical and chemical processes. Commercial production has until recently only been performed by lactic acid fermentation, but some chemical methods have also been discussed for the manufacture of lactic acid (Holton, 1971). Lactic acid is generally produced from glucose, maltose, sucrose, or lactose. Starches, especially those from corn and potatoes, are hydrolysed by enzymes or by acid to maltose and glucose before the lactic acid fermentation (Atkinson and Mavituna, 1991). Sucrose from cane and beet sugar, with containing lactose and maltose, and dextrose from hydrolysed starch are currently used commercially (Vickroy, 1983).

Starch or sugar containing substances can be used as raw material. Starch raw materials have to be degraded first enzymatically or by means of acid, because the lactobacilli do not have amylolytic. This again means a higher cost for addition step which also is brought in impurities (Buchta, 1983). In general, lactic acid bacteria utilise common carbon sources such as glucose, fructose, lactose, maltose, and sucrose for growth and lactic acid production. Starch can not be utilised, but there are several reports that certain members of lactic acid bacteria can use liquefied starch. Lactobacillus delbrueckii is preferred organism to production lactic acid using glucose, fructose, and sucrose but lactose can not be utilised (Atkinson and Mavituna, 1991).

Two different types of lactic acid fermentation from carbohydrates are known to be homolactic fermentation and heterolactic fermentation. Pure lactic or homolactic fermentation is essentially performed by the homolactic lactobacteria. The lactobacilli have the enzyme aldolase and lack of the enzyme phosphoketolase, by glycolytic pathway (Embden-Meyerhof pathway) more than 85% glucose convert to lactic acid (Freeman, 1985). Many lactobacilli species produce levans sucrose in response to growth on sucrose. Depending on the enzymes present in a given strain, the disaccharide sucrose (glucose-1,2--fructose) can be cleaved by two alternatives namely hydrolysis by enzymes invertase or levansucrase yield glucose and fructose (Zubay, 1984; Moat, 1985).

In this research work, the kinetic study of the utilisation of glucose, fructose and sucrose to lactic acid using Lactobacillus delbrueckii is studied.

2. Fundamental

The knowledge of the kinetics of fermentation is necessary in order to size the fermentor and its associated equipment, and this information is normally obtained from laboratory experiment using one to three litres fermentor (Russel, 1987).

Equation 1 Malthus’ law (De Man, et al., 1960), which in the form of gives one of the simplest models belonging to the general form

\[ \frac{dX}{dt} = \mu \cdot X \]  

(1)

In batch fermentation, the specific growth rate is constant and independent of the changing of the nutrient concentration. It is to be expected that growth rate, as any chemical reaction rate, will depend on the concentration of chemical nutrients. Monod-Type relationship is usually expressed the specific growth rate, is usually expressed as a function of the limiting substrate concentration (S)

\[ \mu = \mu_m \left( \frac{S}{K_s + S} \right) \]  

(2)

3. Methodology

The sugars used were analytical grade and supplied by Merck, BDH and Fluka. All chemicals used were analytical grade and used as received. The micro-organism used in this study was Lactobacillus delbrueckii subsp. delbrueckii ATCC 9649 obtained from DSMZ, Germany.

The preparation of inoculum media starts with transferring of the lyophilised culture (Freeze Dried) to a liquid MRS medium. The culture was transferred to solid MRS medium after a visible growth of microorganism was observed which normally takes one day (Mercier et al., 1992; Sakamoto and Komagata, 1996).

The fermentation was carried out in 3-litre fermentor (Biostat B Model) like as Figure 1. The fermentor was equipped with pH, temperature, and dissolved oxygen controllers. The fermentor containing 950 mL substrate was first sterilised at 121°C for 15 minutes. 50 mL of Inoculums was sterilised separately and added aseptically to the fermentor. Anaerobic system were produced by sparging the fermentor by nitrogen 6.5 mL/minute and speed at 50 rpm (Lund et al., 1992). Samples of 10-20 mL were withdrawn from the fermentation broth at regular time interval. The microbial cells were separated by centrifugation.
for dry biomass determination. The supernatant was immediately frozen for further determination of the lactic acid, glucose, fructose and sucrose concentrations (Mercier et al., 1992).

![Bioreactor Biostat B Model](image)

**Figure 1. Bioreactor Biostat B Model**

Cell concentration was measured by constructing a calibration curve of optical Density as a function of dry cell weight. Dry weight was determined by centrifugation at 4000 rpm for 15 minute, washed twice with distilled water, and dried at 103°C for 24 hours and weighed (Aeslichmann and Stockar, 1987). The optical density was measured on spectrophotometer UV-1601 at 620 nm.

The Organic acid content was measured by HPLC (Waters TM 600). A 250 mm X 4,6 mm ID Spherisorb Octyl column (Waters) with UV detector (210 nm) were used. The eluent used was 2 M phosphoric acid at flow rate of 0.8 ml per minute and temperature 25°C. The sugar content was also measured by the same HPLC, using a 300 mm X 4 mm ID. Bondapak/ Carbohydrate column (Waters) with RI detector. The eluent used was a mixture acetoniitrile : water (80:20) at flow rate of 2 mL per minute and temperature 25°C.

This research focused on kinetics of growth microbial. For the determination of the kinetic parameters such as $\mu_{max}$ and $K_s$ as a functional of the initial concentration (S) and cell density (X) like eq. 2. The kinetics parameters were obtained from regression analysis. The equation 2 turned into;

$$\frac{1}{\mu} = \frac{1}{\mu_{max}} + \frac{K_s}{\mu_{max}S}$$  \hspace{1cm} (3)

4. Result and Discussion

In order to understand the fermentation characteristics of different carbon sources, three types of sugars such as glucose, fructose, and sucrose were chosen. The results of the microbial growth, sugar utilisation and lactic acid production are given in Figures 2, 3, 4, and 5.

The profiles of dry cell weight concentration with fermentation time on several of sugar types are given in Figure 2. For a set experimentation, conditions at temperature 40°C, pH 6, inoculum 5%, and stirring speed 50 rpm. The profiles of biomass concentration with time of fermentation show that the lag phases were up to 4 hours for all types of sugars, which are an adaptation period of bacteria to fermentation environment. The exponential growth phase of glucose medium is seen to last 68 hours followed by sucrose and fructose at 116 and 128 hours, respectively. After the exponential phase is stationary phase with the maximum biomass concentration achieved was at 2.28, 1.44, and 1.36 g dry cell weight/l, respectively. This indicates that the best growth of *L. delbrueckii* was obtained when the glucose was used as carbon source, followed by sucrose and fructose.

![Time Dependence of Biomass Concentration during Lactic Acid Fermentation of Glucose, Fructose, and Sucrose](image)

**Figure 2. Time Dependence of Biomass Concentration during Lactic Acid Fermentation of Glucose, Fructose, and Sucrose.**

The glucose, fructose, and sucrose concentrations used were 20 g/L. Figure 3 shows that the sucrose consumption completely utilised at 56 hours, followed by glucose and fructose at 68 and 104 hours, respectively. The consumption pattern of the sucrose during the first 8 hours of fermentation indicates that the glucose and fructose concentrations increased in the medium due to the rate of hydrolysis of sucrose to glucose and fructose was faster than the conversion of these substrate (Figure 4). The maximum concentration of glucose and fructose was 5.82 and 5.14 g/L, respectively. The sucrose, glucose, and
fructose consumption on sucrose fermentation completely utilised at 56, 92 and 116 hours.

Figure 3. Time Course of Glucose, Fructose, and Sucrose Concentration during Lactic acid Fermentation (experimental conditions: T, 40°C; pH, 6.0; inoculum, 5%; and stirring speed, 50 rpm)

Figure 4. Time Course of Sugar Concentration during Lactic Acid Fermentation of Sucrose (experimental conditions: T, 40°C; pH, 6.0; inoculum, 5%; and stirring speed, 50 rpm)

Effect of the sugar types used on the lactic acid production is given in Figure 5. The maximum concentration of lactic acid obtained for glucose medium was 18.25 g/L or 92% of yield at 68 hours. The maximum concentration of lactic acid (yield) for fructose and sucrose obtained were 18.3 g/L (93%), and 18.22 g/L (92%) at 104 and 116 hours, respectively. Although the maximum lactic acid concentration were produced almost similar but the productivity was different. The maximum lactic acid productivity for glucose, fructose and sucrose were 0.27, 0.19, and 0.17 g/l.h, respectively.

Figure 5. Time Course of lactic Acid Concentration during Lactic Acid Fermentation of Glucose, Fructose, and Sucrose (experimental conditions: T, 40°C; pH, 6.0; inoculum, 5%; and stirring speed, 50 rpm)

The kinetic parameters such as \( \mu_{\text{max}} \) and \( K_s \) were obtained from regression analysis of Eqs 3 and plotting \( 1/ \) versus \( 1/S \) are shown in Figure 6, 7, and 8. The values of \( \mu_{\text{max}} \) and \( K_s \) are shown in Table 1.

Figure 6. The Relationship of 1/U (hr) versus 1/Glucose (1/g)
The maximum specific growth rate for *L. delbrueckii* grown on glucose in this work was 0.083 h⁻¹ which is comparative favourably with results obtained by Hakkarainen et al. (1984) who found the maximum specific growth rate of 0.150 h⁻¹.

Mercier et al. (1992) also studied about kinetic of lactic acid fermentation on glucose by *L. amylophilus* which they obtained the maximum specific growth rate of 0.29 h⁻¹ at pH, 6; temperature, 30°C; and stirring speed, 350 rpm. But Tyree et al. (1990) obtained higher maximum specific growth rate than other authors which is 0.722 h⁻¹ using *L. xylosus* with operation conditions of pH: 6.0, temperature: 30°C and stirring speed, 150 rpm. The different results might be due to difference of operation conditions and types of strain used.

The comparison of the saturation constant (Kₛ) on glucose and sucrose utilisation in lactic acid fermentation by the different authors were given in Table 2 and 3.

### 5. Conclusion

During fermentation, indicates that sucrose is hydrolysed to glucose and fructose. Substrate utilisation on 20 g/L sugar concentration completely consumed with sucrose faster than glucose and fructose. Kinetic parameter for maximum specific growth rate in glucose, fructose and sucrose is 0.083, 0.024 and 0.024 (h⁻¹), respectively. The saturation constant is 4.648, 3.410 and 1.343 g/L.

### Notations

- $\mu_{\text{max}}$ = Maximum specific growth rate, h⁻¹
- $\mu$ = Specific growth rate, h⁻¹
- $\frac{dX}{dt}$ = Microbial growth rate, g/L.h
- $K_s$ = Saturation constant, g/L
- S = Substrate concentration, g/L
- t = Time, h
- X = Biomass concentration, g/L
